Introduction: Strain induced mobility enhancement in silicon (Si) FINFETs is attractive because of higher drive current and immunity to short channel effects. Uniaxial compressive strain combined with 110 channel orientation is found to give the best hole mobility enhancement in FINFETs [1]. However, further hole mobility enhancement in (110)<110> Si pFINFETs is limited by strain relaxation issues and commonly observed limited impact of strain on (110) compared to (100) [2]. SiGe channel FINFET is an attractive replacement. Mobility enhancement with FINFET structure(SiGe channel with 25% Ge) that gives the best performance at low power has already been reported [3]. In this paper, we show for the first time that a 157% increase in hole mobility is possible in (110)<110> SiGe FINFETs by increasing Ge content to 50% even in the presence of scattering due to enhanced interface charge density from increasing Dit enhanced alloy scattering [4] and strain relaxation.

Process Technology: Biaxial compressively strained Si₀.₇₅Ge₀.₂₅ layer, 30nm thick, is epitaxially grown on 10nm thick (100) SOI wafers which, upon patterning, produced uniaxially strained 20nm wide, 40nm tall fins with {110}<110> channel orientation. Si fins were also fabricated for comparison. The FINFETs were formed by conventional process [3] and included a neutral/compressively strained contact etch stop layer (CESL) followed by interlayer dielectric (ILD) deposition, contact plug formation and copper metallization. Fig. 1 shows the TEM image of the fin cross section.

Results and Discussions: Finite element method (FEM) simulation in SSGOI₀.₂₅ pFINFETs show an average sidewall stress of 1600 MPa (1% strain) which takes into account relaxation through amorphized S/D regions following the ion implantation. Higher performance of SSGOI₀.₂₅ over (110)<110>-Si (SOI) pFINFETs is evident from Fig. 2. At 10nA/um of Ioff, the SSGOI₀.₂₅ pFINFETs with neutral and compressive CESL show 17% and 46% increase in Ion, respectively, over the silicon counterpart. The subthreshold slope (SS) is slightly lower due increased Dit in SSGOI₀.₂₅ pFINFETs (Fig.3). A 57% net enhancement in hole mobility is seen at sheet carrier density (Ns) of 1x10¹³ cm⁻² (Fig. 4) at 300K from long channel devices. However, the presence of alloy scattering in SSGOI₀.₂₅ negates this enhancement at 77K (Fig. 5). Hole mobility is extracted across temperatures and is then modeled by including the following scattering mechanisms: interface charge scattering (μᵢₑᵢ), surface roughness scattering (μₛᵢₑᵢ), acoustic phonon(μₐᵢ) and optical phonon (μₒᵢ). In SSGOI₀.₂₅ pFINFETs additional mechanism of alloy scattering (μₐₑᵢ) is included the effect of which on SSGOI₀.₂₅ mobility is seen clearly at T=77K (Fig. 5). Bulk coulomb scattering is ignored due to low doping levels in FINFET and remote high-k phonon scattering due to metal gate screening [4]. Excellent agreement between measured and modeled mobility values is seen (Fig 6). Mobility in SSGOI₀.₂₅ and SOI pFINFETs at 300K and at Ns=1x10¹³ cm⁻² is dominated by phonon scattering whereas alloy scattering becomes important in SSGOI₀.₂₅ at 77K. The different mobility components in SSGOI₀.₂₅ are scaled appropriately (using linear extrapolation for the parameters listed in table1) to project the mobility for SiGe channel pFINFETs with higher Ge content(50%). A 157% enhancement is thus estimated at T=300K, Ns=1x10¹³ cm⁻² for SSGOI₀.₅₀ over SSGOI₀.₂₅ assuming 2x increase in the interface states(Fig. 7). At 300K hole mobility is still limited by phonon scattering but at 77K alloy scattering becomes the single dominant mechanism (Fig. 8). Decreasing fin length to 0.5μm results in further strain relaxation (Fig 9) and the net strain retained reduces to 1.5% which will degrade the mobility to 360 cm²V⁻¹s⁻¹.

Conclusions: Experimental and theoretical hole mobility study in uniaxially strained (110)<110>- Si₀.₇₅Ge₀.₂₅ pFINFETs shows that alloy scattering contributes only a small fraction of the overall mobility at 300K but plays a bigger role limiting 77K hole mobility. Increasing the Ge only to 50% increases the strain level. However, the extent of strain relaxation depends on the length of the fin. Fig. 10 shows the measured and projected hole mobility for SiGe FINFETs with 25% and 50% Ge mole fraction. Higher strain induced reduction of effective mass compensates for the increased interface charge density Dit, in SSGOI₀.₂₅ pFINFET and alloy disorder and results in 157% increase in the hole mobility observed at Ns=1x10¹³ cm⁻² and T=300K. Fig. 11 benchmarks the hole mobility in SSGOI₀.₂₅ and SSGOI₀.₅₀ pFINFETs as a function of electrical oxide thickness (TOX) and shows its advantage over relaxed Ge channel MOSFETs. However strain relaxation for shorter length fins need to be addressed using careful layout techniques. High mobility combined with excellent short channel behavior make these devices a promising candidate for future technology node.
